University of Pennsylvania

Being lazy is sometimes vital, but...

...it can lead to unintended consequences.

2017-11-19

Keep Your Laziness In Check

└ Being lazy is sometimes vital, but...

- Ubiquitous in Haskell programming, used in OCaml programming
- (FRP) In the broader world, it is intrinsic in web-based functional reactive programming
- (Spark) and in the field of big-data processing, for example, Spark

... it can lead to unintended consequences.

```
type 'a lazyList =  
  | Cons of ('a Lazy.t *  
             'a lazyList Lazy.t)  
  | Nil
```

2017-11-19

Keep Your Laziness In Check

└ Lazy lists

Lazy lists

```
type 'a lazyList =  
  | Cons of ('a Lazy.t *  
             'a lazyList Lazy.t)  
  | Nil
```

- In this talk, we'll analyze functions that operate over lazy data structures
- In OCaml, Lazy is a standard library module that provides operators for suspending computations into lazy values
- for instance, a lazy list like this
- A lazy list is just a list with all of its parameters wrapped in a lazy computation

```
let enQ a (front, back) =  
  (front, lazy (Cons (lazy a, back)))  
  
let deQ (front, back) =  
  match Lazy.force front with  
  | Cons (a, front') -> (a, (front', back))  
  | Nil ->  
    let Cons (a, front') = reverseLazyList back  
    in (a, (front', lazy Nil))
```

### └ Lazy queues

2017-11-19

Lazy queues

```
let enQ a (front, back) =  
  (front, lazy (Cons (lazy a, back)))  
  
let deQ (front, back) =  
  match Lazy.force front with  
  | Cons (a, front') -> (a, (front', back))  
  | Nil ->  
    let Cons (a, front') = reverseLazyList back  
    in (a, (front', lazy Nil))
```

- As a micro example to motivate why thinking about laziness can be non-trivial, let's look at this queue
- This has amortized  $O(1)$  performance cost.
- This queue is lazy as long as you don't empty the front, then it is fully lazy in the structure of the back list. It only forces the spine of the back list when the front list is emptied.

# Wouldn't it be nice to QuickCheck laziness?

2017-11-19

## Keep Your Laziness In Check

└─Wouldn't it be nice to QuickCheck laziness?

Wouldn't it be nice to QuickCheck laziness?

Traditional property-based testing (such as QuickCheck):

- ✓ Great for testing functional correctness
- ✓ Write a specification, fuzz inputs to functions to automatically test against that specification
- ✗ Can only specify and check functional correctness properties

If we were able to **specify** and **observe** laziness, we could treat it *just like* functional correctness.

Traditional property-based testing (such as QuickCheck):

- ✓ Great for testing functional correctness
- ✓ Write a specification, fuzz inputs to functions to automatically test against that specification
- ✗ Can only specify and check functional correctness properties

If we were able to **specify** and **observe** laziness, we could treat it *just like* functional correctness.

- PBRT is a technique for randomized testing which allows users to write down an executable specification for a function and test whether it holds for randomly generated inputs.
- QuickCheck gives functional correctness
- But laziness can't currently be observed by tools like QuickCheck
- Laziness is not generally considered part of functional correctness much like how asymptotic runtime is not part of functional correctness because they are not directly observable
- What if we make it observable? Then it's just part of functional correctness!

# StrictCheck

“We actually can do that thing.”

2017-11-19

Keep Your Laziness In Check

**StrictCheck**

“We actually can do that thing.”

**Figure 1:** Instrumented List

```
instrumentListWithRef : int ref
  -> 'a lazyList
  -> 'a lazyList
```

### Observing strictness

- Hengchu:
- `instrumentListWithRef` clones the structure of the original list, and attaches a lazy effectful computation to each constructor in the list. So as the list is evaluated, each step of evaluation triggers one update

# Strictness doesn't exist in a vacuum

**Figure 2:** No Demand

Keep Your Laziness In Check

└ Strictness doesn't exist in a vacuum

Strictness doesn't exist in a vacuum

Figure 4: Spine Strict

- These pictures are illustrations of a demand context on a lazy list
- This gives us an easy way to observe the strictness behavior of a context
- While these pictures might look like a data structure, they are meant to describe the behavior of a context of evaluation on a lazy data structure of this shape

### └─Demanding an answer, lazily

```
demandCount context f xs =  
  let count = ref 0  
    observableList =  
      instrumentListWithRef count xs  
  in context (f observableList); !count
```

- demandCount takes a context, and a function that operates over lists and the input list
- it applies instrumentListWithRef on the input list, producing an observableList, and applies the function and context over the observableList, triggering the injected instrumentation code
- context is exerting some demand on the output of f

```
demandCount context f xs =  
  let count = ref 0  
    observableList =  
      instrumentListWithRef count xs  
  in context (f observableList); !count
```

```
> let f xs = takeLazy (lazy 6, xs)
> let list = toLazyList [1; 2; 3; 4; 5]
```

## Examples of demandCount

```
> let f xs = takeLazy (lazy 6, xs)
> let list = toLazyList [1; 2; 3; 4; 5]
```

2017-11-19

1
> demandCount spineStrict f list
```

2017-11-19

Keep Your Laziness In Check

└─ Examples of demandCount

```
> let f xs = takeLazy (lazy 6, xs)
> let list = toLazyList [1; 2; 3; 4; 5]
> demandCount noDemand f list
0
> demandCount firstCons f list
1
> demandCount spineStrict f list
```

```
> let f xs = takeLazy (lazy 6, xs)
> let list = toLazyList [1; 2; 3; 4; 5]
> demandCount noDemand f list
0
> demandCount firstCons f list
1
> demandCount spineStrict f list
5
```

### └─ Examples of demandCount

```
> let f xs = takeLazy (lazy 6, xs)
> let list = toLazyList [1; 2; 3; 4; 5]
> demandCount noDemand f list
0
> demandCount firstCons f list
1
> demandCount spineStrict f list
5
```

- Just some examples showing demandCount
- takeLazy is a function that takes the specified number of elements from a lazy list and returns a lazyList
- Note that we simply treat `f` as a black box
- We don't need to know anything more about `f` other than the fact it typechecks with demandCount!

## Keep Your Laziness In Check

2017-11-19

- └ Beyond lists and numbers

?

?

- Kenny:
- Arbitrary lazy algebraic datatypes
- This gives us a bare example that counts the number of cons cells forced, but what if we want more fine grained information of arbitrary algebraic data types?
- Numbers can't directly capture the structure of a tree, so it can't capture the nodes of a tree that get forced in a computation

# Reifying demand on lazy lists

```
type 'a lazyList =  
  | Cons of ('a Lazy.t *  
             'a lazyList Lazy.t)  
  | Nil
```

---

```
type 'a thunk = T | E of 'a
```

```
type 'd listDemand =  
  | ConsD of ('d thunk *  
              'd listDemand thunk)  
  | NilD
```

```
type intDemand = IntD
```

## Keep Your Laziness In Check

└ Reifying demand on lazy lists

- Now, we can exactly characterize a demand on a list of Ints by composing the type ListDemand and IntDemand
- The type ListDemand is a reification of the demand placed upon a lazy list during the course of evaluation in some context

Reifying demand on lazy lists

```
type 'a lazyList =  
  | Cons of ('a Lazy.t *  
             'a lazyList Lazy.t)  
  | Nil  
-----  
type 'a thunk = T | E of 'a  
  
type 'd listDemand =  
  | ConsD of ('d thunk *  
              'd listDemand thunk)  
  | NilD  
  
type intDemand = IntD
```

2017-11-19

```
type 'd listDemand =
  | ConsD of ('d thunk *
              'd listDemand thunk)
  | NilD
```

```
type intDemand = IntD
```

---

```
ConsD (T,
       ConsD (E IntD,
              ConsD (T, T)))
```

```
ConsD (E IntD,
       ConsD (T,
              ConsD (E IntD, E NilD)))
```

```
type 'd listDemand =
  | ConsD of ('d thunk *
              'd listDemand thunk)
  | NilD

type intDemand = IntD

ConsD (T,
       ConsD (E IntD,
              ConsD (T, T)))

ConsD (E IntD,
       ConsD (T,
              ConsD (E IntD, E NilD)))
```

- The 2nd Int is forced, and we force 3 cons cells, we don't force anything in the rest of the list
- The 1st and 3rd Int is forced, and the list's spine is forced
- Note that these represent concrete observations instrumented on given inputs, they do not represent the general behavior of contexts

```
type 'a lazyTree =  
  | Node of ('a lazyTree Lazy.t *  
             'a Lazy.t *  
             'a lazyTree Lazy.t)  
  | Leaf  
  
type 'd treeDemand =  
  | NodeD of ('d treeDemand thunk *  
             'd thunk *  
             'd treeDemand thunk)  
  | LeafD
```

### └ Reifying demand on lazy trees

- The demand type for a binary Tree
- We can either demand the value at an internal node, or one of the subtrees
- The demand type represents all of the possible prefixes/subshapes of its corresponding data type

```
type 'a lazyTree =  
  | Node of ('a lazyTree Lazy.t *  
             'a Lazy.t *  
             'a lazyTree Lazy.t)  
  | Leaf  
  
type 'd treeDemand =  
  | NodeD of ('d treeDemand thunk *  
             'd thunk *  
             'd treeDemand thunk)  
  | LeafD
```

```
type 'd listDemand =  
  | ConsD of ('d thunk *  
              'd listDemand thunk)  
  | NilD
```

```
type 'd treeDemand =  
  | NodeD of ('d treeDemand thunk *  
              'd thunk *  
              'd treeDemand thunk)  
  | LeafD
```

### └ Comparing demands on lazy lists and trees

- Notice the similarity between ListDemand and TreeDemand with their corresponding data types
- In general, the demand type of a data type simply interleaves a Thunk at every constructor field

```
type 'd listDemand =  
  | ConsD of ('d thunk *  
              'd listDemand thunk)  
  | NilD  
  
type 'd treeDemand =  
  | NodeD of ('d treeDemand thunk *  
              'd thunk *  
              'd treeDemand thunk)  
  | LeafD
```

```
demandList : 'b context -> (int lazyList -> 'b)
           -> int lazyList
           -> ('b * intDemand listDemand thunk)

demandTree : 'b context -> (int lazyTree -> 'b)
           -> int lazyTree
           -> ('b * intDemand treeDemand thunk)
```

```
demandList : 'b context -> (int lazyList -> 'b)
           -> int lazyList
           -> ('b * intDemand listDemand thunk)

demandTree : 'b context -> (int lazyTree -> 'b)
           -> int lazyTree
           -> ('b * intDemand treeDemand thunk)
```

```
demandList : 'b context -> (int lazyList -> 'b)
           -> int lazyList
           -> ('b * intDemand listDemand thunk)
```

```
demandTree : 'b context -> (int lazyTree -> 'b)
            -> int lazyTree
            -> ('b * intDemand treeDemand thunk)
```

---

```
demand      : 'b context -> ('a -> 'b) -> 'a
            -> ('b * ('a DEMAND) thunk)
```

### └ Observing demand, generically

- There is a determinate relation between a lazy data structure and its demand representation
- We return a Thunk of demand because the input might not be demanded at all
- We expect that the 'a parameter is some kind of lazy structure, and 'b is also some kind of lazy structure
- We use generic programming to implement the DEMAND type for all algebraic data types

```
demandList : 'b context -> (int lazyList -> 'b)
           -> int lazyList
           -> ('b * intDemand listDemand thunk)

demandTree : 'b context -> (int lazyTree -> 'b)
            -> int lazyTree
            -> ('b * intDemand treeDemand thunk)

-----

demand      : 'b context -> ('a -> 'b) -> 'a
            -> ('b * ('a DEMAND) thunk)
```

```
type 'a lazyList =
  | Cons of ('a Lazy.t *
             'a lazyList Lazy.t)
  | Nil

let deQ (front, back)
  : ('a Lazy.t * ('a lazyList Lazy.t *
                  'a lazyList Lazy.t)) =
  match Lazy.force front with
  | Cons (a, front') -> (a, (front', back))
  | Nil ->
    let Cons (a, front') = reverseLazyList back
    in (a, (front', lazy Nil))
```

```
type 'a lazyList =
  | Cons of ('a Lazy.t *
             'a lazyList Lazy.t)
  | Nil

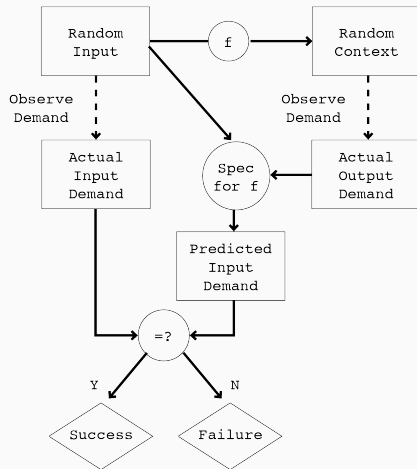

let deQ (front, back)
  : ('a Lazy.t * ('a lazyList Lazy.t *
                  'a lazyList Lazy.t)) =
  match Lazy.force front with
  | Cons (a, front') -> (a, (front', back))
  | Nil ->
    let Cons (a, front') = reverseLazyList back
    in (a, (front', lazy Nil))
```

```
let spec_deQ (front, back) (dInt, (dFront, dBack)) =  
  match Lazy.force front with  
  | Cons (_, _) ->  
    (E (ConsD (dInt, dFront)), dBack)  
  | Nil -> (E NilD,  
           spineStrictAs back  
             (pad (length back - lengthD dFront)  
                  (reverseD (ConsD dInt dFront)))))
```

### └ First-order specifications

```
let spec_deQ (front, back) (dInt, (dFront, dBack)) =  
  match Lazy.force front with  
  | Cons (_, _) ->  
    (E (ConsD (dInt, dFront)), dBack)  
  | Nil -> (E NilD,  
           spineStrictAs back  
             (pad (length back - lengthD dFront)  
                  (reverseD (ConsD dInt dFront)))))
```

- Having demonstrated how to reify demand behaviors into value, we now need to figure out how to write down a specification to check if whether a particular run of the program has the specified laziness according to the specification
- Specifications go backwards from demands on the output to demands on the inputs of the function. This is because how much input is demanded depends on how much output is demanded, hence the arrows go the other way.
- Specifications are passed in the actual values of the inputs because their demand behaviors can be dependent on those inputs
- spineStrictAs takes a lazy data structure, and unions a spine strict demand corresponding to the whole structure with another demand on some sub-part of that structure

### Connecting specification with observation

- We randomly fuzz the inputs to the function, and
- We can generate random contexts that exert non-trivial demand on the output values
- We observe the demand on the input and also the demand on the output, so we can just straightforwardly compare that to what the specification expects.

With **StrictCheck**, you will be able to:

- **Observe** laziness from within Haskell
- **Specify** laziness properties as Haskell functions
- **Test** implementations against those specifications
- **For all types**,<sup>1</sup> including higher-order functions and data types containing functions

The implementation is a work in progress.

---

<sup>1</sup>Simple (i.e. non-indexed, non-existential) types
